

# BitVM

Off-chain Bitcoin Contracts

# Motivation

- Blockchains don't scale
- Lightning doesn't quite scale
- Can we scale Bitcoin to billions of users?

# Envisioning an Ideal World

- 100 - 1000x higher throughput
- Free market of L2s (zk-rollups, sidechains, zkCoins, ...)
- Rapid innovation / cheap experimentation
- All L2s interconnected via LN
- Possible, but we need bridges!

# Overview

- Stateful Bitcoin Scripts
- BitVM architecture
- BitVM bridges

# Stateful Bitcoin Scripts

# Bitcoin Script

- Satoshi disabled all the fun opcodes
- Reduced to minimum
- But enough interesting opcodes are left
- Scripts can be up to 4mb
- Bitcoin Script code golf

# Stateful Bitcoin Scripts

- Idea: If we could sign a value...
- Enforcing the same value for  $x$  in script1 and script2
- Punish equivocation
- How to sign a value though?
- We don't have CSFS...

# Lamport Signatures

- Conceptually very simple
- Require only hash functions
- Possible in Bitcoin Script
- Main drawback: large
- But one can sign a u8, u32, u160

# Lamport Signature for a 1-bit Message

```
OP_HASH160
OP_DUP

<0xf592e757267b7f307324f1e78b34472f8b6f46f3>    // This is hash1
OP_EQUAL
OP_DUP

OP_ROT
<0x100b9f19ebd537fdc371fa1367d7ccc802dc2524>    // This is hash0
OP_EQUAL

OP_BOOLOR
OP_VERIFY

// Now the value of the bit commitment is on the stack. Either "0" or "1".
```

# BitVM Architecture

# BitVM the paradigm

- Tries to keep things off-chain (like LN)
- 2-party setting: prover and verifier
- Optimistic computation
- Disprove a faulty result (much easier than execution)
- Tree++

# Tree++

- Language to express Bitcoin Contracts in graphs of transactions
- Templating language for Script
  - Evaluate constant expressions
  - Unroll loops
  - Compose functions
- Statefulness via Lamport signatures (u8, u32, u160, ...)
- Composite opcodes (xor, shift, mul, blake3, ...)
- Connector outputs
- Potentially large scripts, large Taptrees, and large TX graphs

# BitVM the Bitcoin VM

- Don't want to hand-craft and hand-optimize a low-level circuit for every application
- Build some generic VM
- Succinctly disprove any faulty result
- Ideally: RISC-V architecture

# BitVM Specs

- Basic instruction set rv32i
- Compile target for clang, gcc, LLVM
- Use existing C / C++ / Rust / ... libraries
- STARK & SNARK verifiers, etc...

# BitVM Detailed Specs

- Max steps:  $2^{32}$
- Memory:  $2^{32} * 4$  bytes ~ 17GB
- Worst case: ~40 rounds of challenge & response
- "Court case" runs for up to half a year
- In total: ~150kb of Scripts
- Worst case is heavily disincentivized
- Likely never happens in real world applications

Vicky and Paul agree in their contract on some program and the initial state of the VM, `traceRoot[0]`

### Implicit Values

$$n_i = 2^{**i} + \text{sum for } j > i \text{ each } b_j * 2^{**j}$$

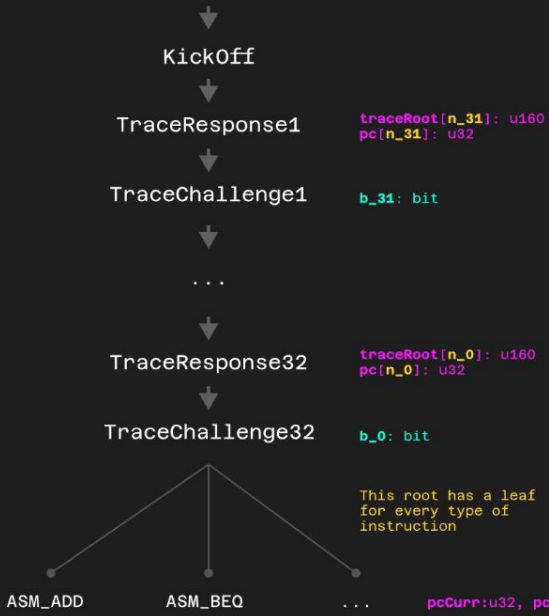

$$N = \text{sum for } j < 32 \text{ each } b_j * 2^{**j}$$

|            |           |           |           |           |           |           |           |           |     |   |          |          |          |          |
|------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----|---|----------|----------|----------|----------|

| $n_{31} =$ | 1         | 0         | 0         | 0         | 0         | 0         | 0         | 0         | 0   | 0 | 0        | 0        | 0        | 0        |
| $n_{30} =$ | $b_{31}$  | 1         | 0         | 0         | 0         | 0         | 0         | 0         | 0   | 0 | 0        | 0        | 0        | 0        |
| $n_{29} =$ | $b_{31}$  | $b_{30}$  | 1         | 0         | 0         | 0         | 0         | 0         | 0   | 0 | 0        | 0        | 0        | 0        |
| $n_{28} =$ | $b_{31}$  | $b_{30}$  | $b_{29}$  | 1         | 0         | 0         | 0         | 0         | 0   | 0 | 0        | 0        | 0        | 0        |
| $n_{27} =$ | $b_{31}$  | $b_{30}$  | $b_{29}$  | $b_{28}$  | 1         | 0         | 0         | 0         | 0   | 0 | 0        | 0        | 0        | 0        |

|            |          |          |          |          |          |          |          |          |          |          |          |     |          |          |          |   |
|------------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|-----|----------|----------|----------|---|
| $n_{31} =$ | $b_{31}$ | $b_{30}$ | $b_{29}$ | $b_{28}$ | $b_{27}$ | $b_{26}$ | $b_{25}$ | $b_{24}$ | $b_{23}$ | $b_{22}$ | $b_{21}$ | ... | 1        | 0        | 0        | 0 |
| $n_{30} =$ | $b_{31}$ | $b_{30}$ | $b_{29}$ | $b_{28}$ | $b_{27}$ | $b_{26}$ | $b_{25}$ | $b_{24}$ | $b_{23}$ | $b_{22}$ | $b_{21}$ | ... | $b_{31}$ | 1        | 0        | 0 |
| $n_{29} =$ | $b_{31}$ | $b_{30}$ | $b_{29}$ | $b_{28}$ | $b_{27}$ | $b_{26}$ | $b_{25}$ | $b_{24}$ | $b_{23}$ | $b_{22}$ | $b_{21}$ | ... | $b_{31}$ | $b_{30}$ | 1        | 0 |
| $n_{28} =$ | $b_{31}$ | $b_{30}$ | $b_{29}$ | $b_{28}$ | $b_{27}$ | $b_{26}$ | $b_{25}$ | $b_{24}$ | $b_{23}$ | $b_{22}$ | $b_{21}$ | ... | $b_{31}$ | $b_{30}$ | $b_{29}$ | 1 |

$N = b_{31} b_{30} b_{29} b_{28} b_{27} b_{26} b_{25} b_{24} b_{23} b_{22} b_{21}$  ...  $b_3 b_2 b_1 b_0$  = "last correct VM step"  
 $N+1 =$  "first incorrect VM step"

Note that some  $n_i$  must equal  $N+1$ . Thus, Vicky has witnessed a commitment of Paul to his faulty `traceRoot[N+1]`

# BitVM Bridges

# BitVM Bridges

- Bridge BTC to any other system
- Idea: a bit clunky is fine
- Bridge is used rarely. Only large amounts
- End users use cross-chain swaps

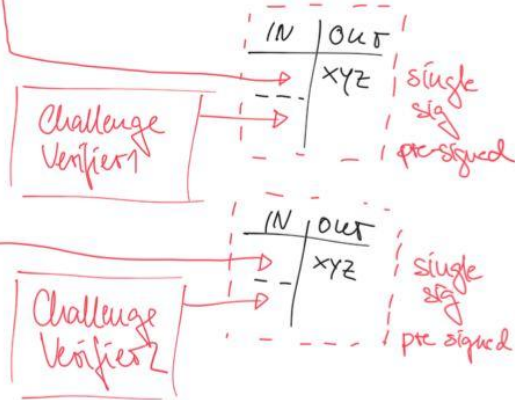

# BitVM Bridge Guarantees

- A Federation, but a single honest member suffices
- Guarantees that the bridge is safe and live
  - safe: nobody can steal the deposit
  - live: you can't stop a valid peg-out
- Large federations: +100 members
- *You* can be a member. Then you don't have to trust anyone

# Peg-In

| IN               | OUT               |
|------------------|-------------------|
| 100 BTC<br>Alice | 100 BTC<br>n-of-n |

# Peg Out

# Limitations

- Complexity
- Balancing incentives: Loser has to pay winner's fees + bounty
- If incentives are balanced the chain is not needed
- Potentially capital intensive
- But no 1:1 collateral required
- For every peg-in all N parties have to pre-sign N peg-out TXs
- Federation can censor peg-ins

# Summary & Outlook

- BitVM enables more complex Bitcoin contracts
- Use case: trust-minimized bridges for rollups, sidechains, L2s, ...
- Limitation: practical but clunky
- Requires no softfork
- Toy version ready this month
- Reckless mainnet this year
